Supplementary Figure 1. Specificity of α Hes6 antibody.

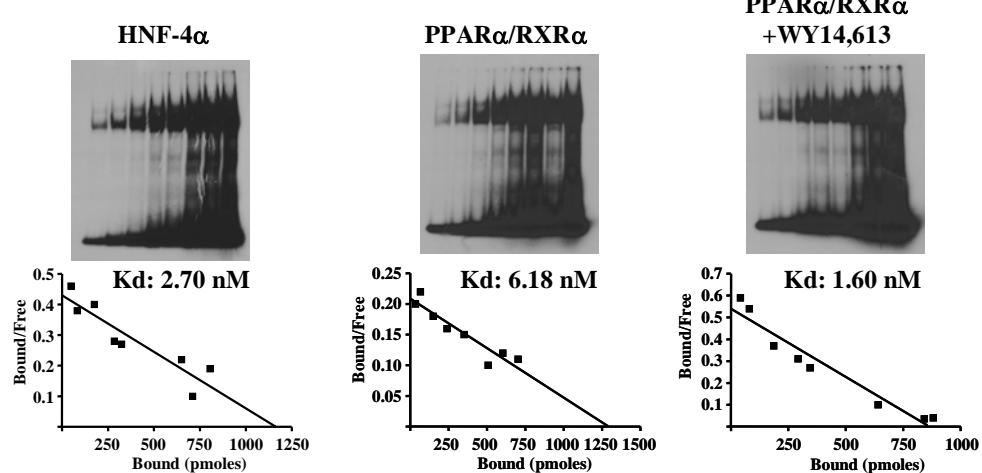

(Left panels) Nuclear extracts (~ 40 μ g protein per lane) from two wild-type mouse livers were analyzed in western blots using α Hes6 antibody (1:2000 dilution) in the absence or presence of 1 μ g recombinant Hes6 competitor protein.

(Right panel) Nuclear extracts from livers were prepared from livers by standard procedures or from livers after crosslinking by the procedure used for ChIP. After immunoprecipitation with α Hes6 antibody, Hes6 protein was detected by ECL in western blots performed by the same antibody.

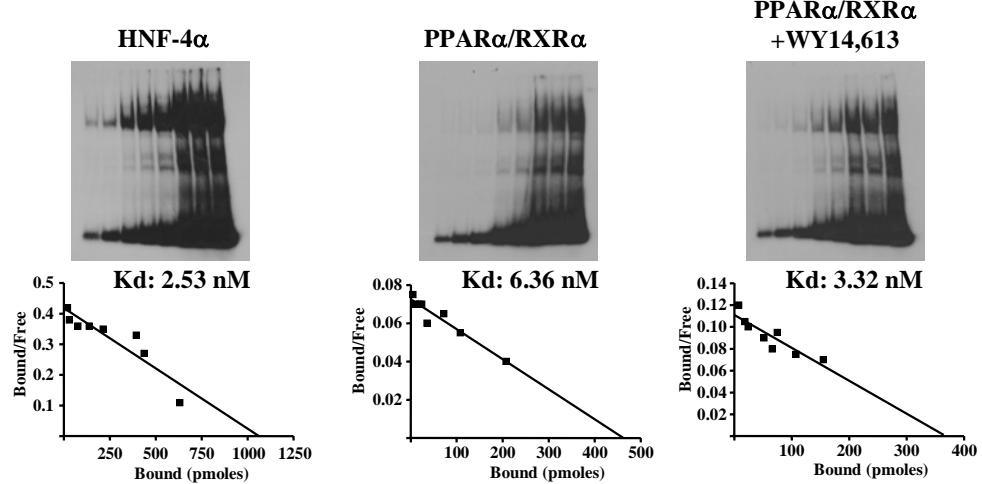

Supplementary Figure 2. Comparative analysis of hepatic mRNA levels of fatty acid metabolism genes in the livers of *HNF4-LiVKO*, *PPAR α -KO* and double *HNF-4-LiVKO/PPAR α -KO* mice. Bars represent mean values and standard deviations of mRNA levels relative to wild-type values (n=3 per group).

A. ACOT1 enhancer oligo

B. CPT1 distal promoter oligo

Supplementary Figure 3. DNA binding affinity measurements of HNF4 α and PPAR α with ACOT1 and CPT1 promoter elements.

The dissociation constant values were obtained from binding reactions containing constant amount of protein extracts from cells transfected with the indicated cDNAs and increasing concentrations of radiolabeled oligonucleotide probes. After electrophoresis bound and free probes were quantitated using STORM phosphoimage analyzer. Linear regression curves were obtained by plotting the amount of bound probe versus bound/free. The Kd values were calculated from the slopes using Graphpad Prism 4 program.
